

ABSTRACT OF THE DISCLOSURE

[0032] A brace for protecting a pivoting joint situated between a first and second limb structure. The brace includes upper and lower frame members linked by a joint member, with each frame member having a cuff for encompassing a portion of each limb structure. Brace retention is accomplished with respective upper and lower securement members each including a medial piece and a lateral piece each attached at respective outside edges thereof to an elastomeric central piece disposed there behind. Respective inside edges of the medial and lateral pieces have a tightening member for drawing the edges toward each other. The respective outside edges of the medial and lateral pieces are releasably attached to respectively adjacent frame and cuff sites with quick-release connectors releasable substantially without increased pressure on the limb structure. Such quick-connect and quick-disconnect operability provides proper brace placement without awkward, and potentially incorrect, brace orientation.
